

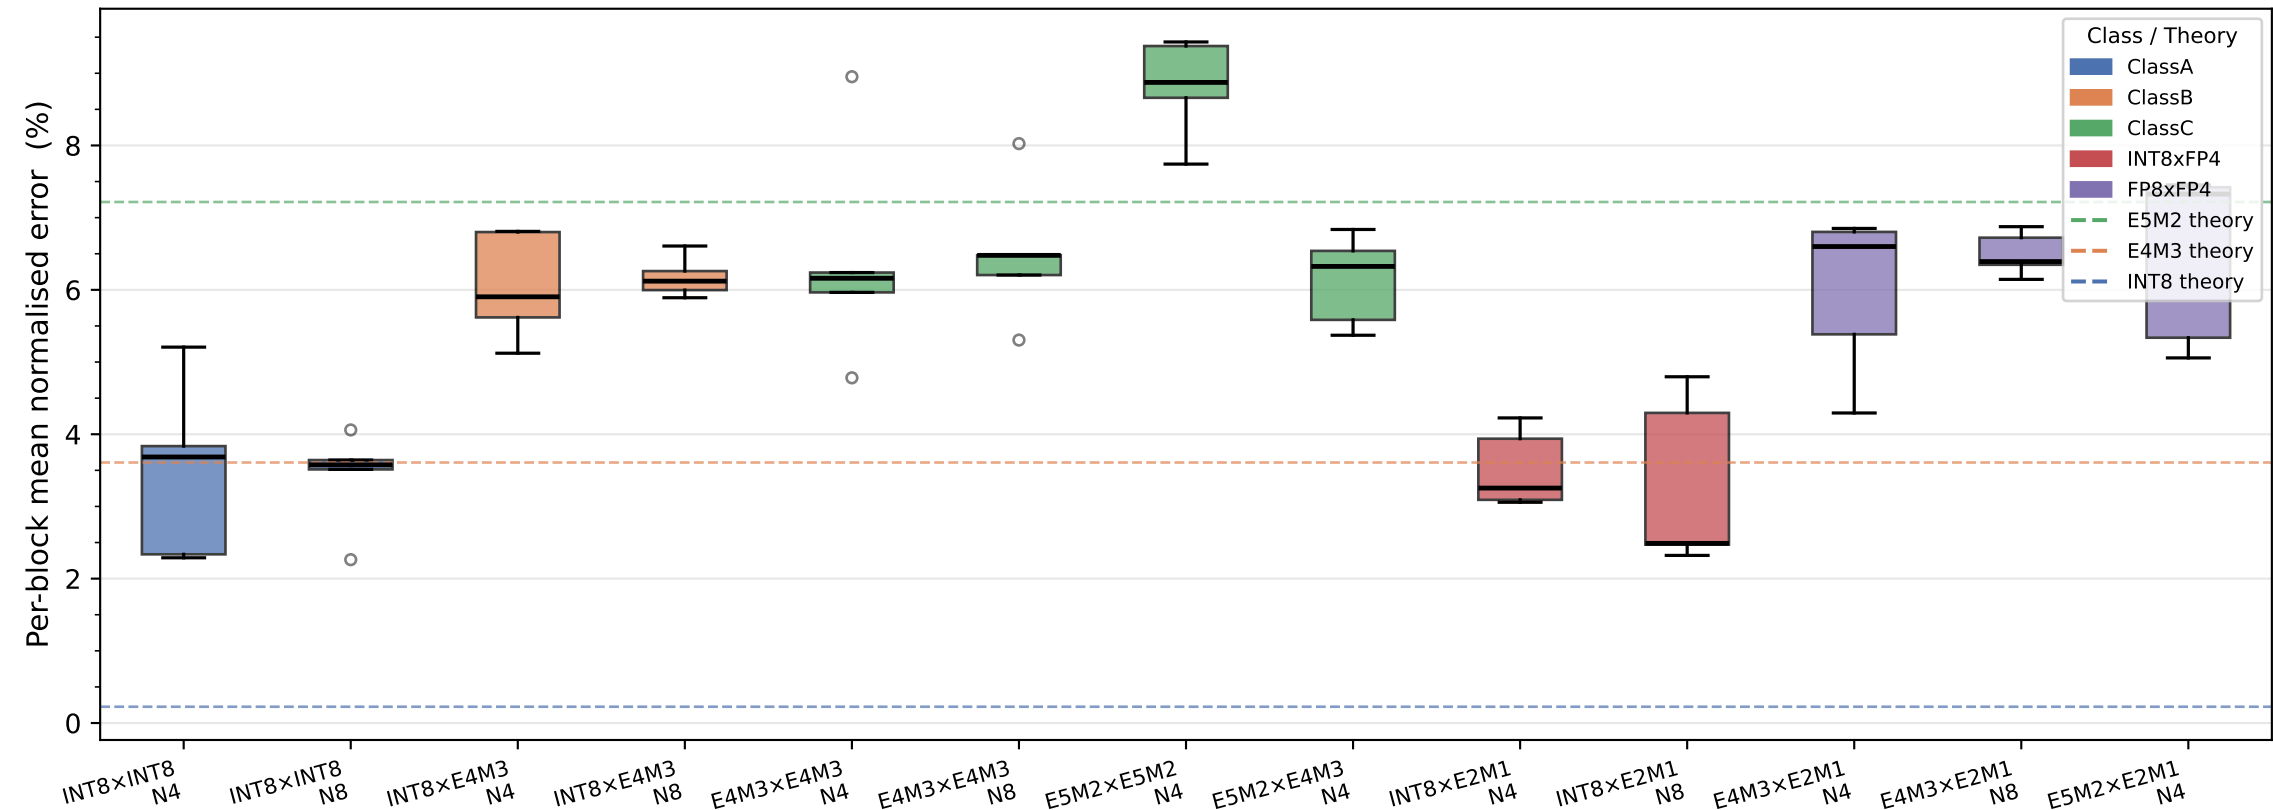

Fig 2 — Requant noise floor distribution across K values
(accMantBits=23 / FP32 accumulator; pure requantisation noise)

Note: dashed lines are theoretical uniform-quantisation noise $\sigma \approx 2^{-(m+1)}/\sqrt{3}$ for m mantissa bits. Measured values agree within 10% — confirming no abnormal saturation or outlier blocks (max/mean < 5 for all configs). INT8 output has lower normErr than E4M3 despite wider bit-width because INT8 scale covers a wider absolute range, reducing relative error.
